DEOC期ETION OE A NEW ELOUNEER (ERATVSOMATICETIIS STOMHAS), FROM TUEE COASTOF CAHEEOFNLA.
Figy DAVID S. JoBEDAN amed CHARLES MI. GIELBERT.

Body extremely elongate for the family, thin, and strongly compressed. Head rather long and slender; the snout somewhat pointed. Mouth extremely large and oblique, the lower jaw included; the maxillary rery long and sleuder, reaching much beyond the eye, its length about half that of the head. Premaxillary in front above the level of the lower eye.

Teeth in the upper jaw anteriorly long, slender, and wide-set. Some of the teeth rery freels depressible, the larger ones scarcely movable. Posteriorly the teeth are much smaller, close-set, and fixed in tro rows; the inner row continuous with the larger anterior series, the onter row extending outside of some of the enlarged teeth.

Teeth in the lower jaw very sharp and slender, long, aud wide-set, alternating with shorter ones, which are very freely depressible. Outside of the larger teeth is a series of small, fixed, close-set teeth. The larger teeth in each jaw are distinctly arrow-shaped. Pharyngeal teeth apparently in one row.

Eyes large, dextral, their anterior margins abont even with each other; the upper eye larger and directed obliquely uprard. A conspicuous ocnlar ridge about the upper eye, becoming continuons with the lateral line. Interorbital space narrow, not half the width of the eye, scaly, as is the space in front of it. Cheeks wide, the posterior edge of the preopercle free. Operele rather short and weak. Premaxillary protractile, capable of little protrasion.

Gill-rakers long and strong, about $t+13$ in number, the longest more than half the diameter of the eye.

Scales rery small and thin, irregularly arranged, their margins weakly ciliated, in about 13.5 transverse series; about 100 tubes in the course of the lateral line. The lateral line is nearly straight, gently ascending in front. No accessory lines. Scales on blind side similar.

Dorsal fin begiming just behind the middle of the eye, its rays low, especially anteriorly, its greatest height considerably behind the midalle. Candal fin somewhat forked. Anal fin higher than the dorsal, its highest rays about midway. No spine before anal. Caudal peduncle long and slemder, abont as long as the maxillary. P'ectoral fins short, the one on the right or eyed side longest, its length nearly equal to that of the maxillary. Veutral fins very short, reaching jast past the rent.

Fin rays: 1). 101; A. s.s.
Color plain brown, with darker ponctulations. Left side white, the many dark points giving it a soiled appearance. Fins dusky.
This species is known to us from one example over a foot long, bought in the San Fruncisco market, and taken just outside the Golden Gate. It doubtless reaches a much larger size, and the adult is probably less slender than this example.

It differs from its congener, the Greenland Halibnt, Plutysomatichthys hippoglossoides, of the North Atlantic, in the slenderer body, larger month, longer gill-rakers, and narrow interorbital space, but the two appear to agree in all respects of generic value.

We regret the necessity of using the clumsy and inappropriate generic name Platysomatiehthys for these fishes instead of the name lieinhardtius proposed by Professor Gill. The former name, althongh later in date, has priority of definition.*

Table of measurements of Plutysomatichthys stomias.

[^0]PROCEEDINGS OF LNITED STATES NATIONAL MUSEUM.
Length of mandible ..... 168
Greatest width of maxillary ..... 03
Diameter of orbit ..... 07
Distance from snout to dorsal ..... 116
Length of base of dorsal ..... 79
Greatest height of dorsal ..... 094
Distance from siont to anal ..... 346
Length of base of anal ..... 615
Height of longest ray ..... 105
Length of middle caudal rass ..... 142
Length of outer candal rass ..... 185
Distance from shont to pectoral ..... 295
Length of peetoral (right site) ..... 128
Distance from smont to ventral ..... $1: \%$
Length of nentral ..... 057
Dorsal rays ..... 101
Anal rays ..... -5
Number of tubes in lateral line. ..... 93San Francisco, Cal., Mareh 1, 1880.
 

Borly mather elongate, deepest at the shoulders; the protile thence to the occiput convex, the occipital and interorbital region considerably depressed; hody tapering backwards from the shonkers into a short and slender caudis peduncle.

Hoad small, thick, the snout blunt. Month mather large, little oblique, the lower jaw inchuded; maxillary slightly passing the rertical from the front of the orbit: premaxillay anteriorly on a level with the inferior margin of the pupil. Eye very large, its diameter about one-third the length of the head ; interorbital region very broad. Lower lip with a narrow fremm, above which its margin is narrowly free.

Tecth large, in a single row, much as in C'ymutogaster fremutus, but bhuter, slightly compressed and truncate at tip, somewhat incisor-like, the edge, however, entire. Teeth few and distant, about $\frac{12}{8}$; none on the sides of the lower jaw. They are larger, blmonter, and more wide-set than in Cymatoguster aggregutus.

Scales on the cheeks in three series below.
Gill-rakers small and weak, much as in Cymutoguster aggregutus, enrved and apparently smooth.

Scales large, but rather sualler than in any of the related species, 50 in the comse of the lateral line.

Spinous dorsal high; the first spine two-fifthe the length of the highest; the sixth to tenth of nearly equal height, and higher than the soft rass. Anal fin with the base oblique and convex, the spines rather strong, more or less curverl, as in Abeona.

[^0]:    * In a paper written later, but hy accident printed earlier (Proc. U. S. Nat. Mus., 1880,51 ), we have recognized this species as the type of a distinct genns, Atheresthes.
